

Excel to XML v7

Description

Excel to XML will let you submit an Excel file in the format .xlsx to a Switch flow where it will be converted to XML and/or metadata sets. It will accept Excel files with multiple sheets. You have different options of output either as XML-files or to pickup the Excel data and embed as a dataset in the same way as the XML-pickup element works.

New in version 7 now you can output one XML-file for each row in the Excel sheet. Restricted to Excel files with only one sheet.

Version adds two Private Data sets

To just output XML-files that later can be imported in to InDesign for automatic production of documents from the XML-data works without the Metadata module. This works in a simple situation where you just import the XML-file to InDesign as long as you don't need any information in the XML for controlling InDesign.

You can also pickup the data in the Excel document and embed it in a job file that you send in alongside with the Excel document. In this case you need the Metadata module and the element Opaque pickup in the flow before the Excel to XML app.

Compatibility

Switch 13 update 1 and higher. Windows or Mac OSX.

Compatibility third-party applications

This app uses Python to process scripts, for Windows Python is included in the app and for Mac OSX it uses the Python that is in Mac OSX.

You don't need to install any other applications for this app but the Python script itself needs to be downloaded and stored on your system. The conversion from Excel xlsx to csv is performed by this open source Python script. Due to licensing you have to download that script yourself and put in a folder of your choice. Then in the properties you can select this script file. Without it the app will not work. It is tested and runs with Python version 2.7x.

Connections

Excel to XML can have several input connections but there is only one outgoing connection. No settings are available of the outgoing connection.

Properties detailed info

If you are using this app to just output XML files you just have to set the properties in the way you like. If you want to send Excel files along job files you need the element "Opaque pickup" that are included in the Metadata module. The reason for the "Opaque pickup" is to be able to pair a job file with the data in the Excel file.

You will get two datasets with this option

Flow element properties

- Path to script file
 - Select the Python script file named “xlsx2csv.py”
- Encoding in XML
 - Choose between UTF-8 or iso-8859-1. In some cases on Windows text with special characters will be encoded in iso-8859-1. If the encoding is set to UTF-8 in such cases the resulting XML will not parse correctly or not at all.
- Root node name
 - Give the root node a name of your choice, default is **csv**.
- Row node name
 - Give the row node a name of your choice, default is **row**.
- Column node name
 - Give the column node a name of your choice, default is **col**.
- Output mode
 - Convert Excel to XML.
 - Attach opaque Excel data as XML dataset.
Will add the Excel file itself as an Opaque dataset and the data in the Excel file will be added as an XML dataset to the job file for later use in the flow.
- One or many XML-files
 - One XML file for every sheet.
 - One XML file for all sheets.
 - One XML file for each row.
 - First part of file name, column #
You can name the output file with values from the column. The property should be the column number. Default is 1
 - Second part of file name, column #
This property will let you add another columns value to the file name, the two values will be separated with an underscore. Default is empty
If you leave this field empty only the first part will be used.
 - The file name will also get a suffix of the row number to prevent over writing of duplicates, it will be separated with a underscore.
- Attach opaque Excel data as XML dataset
 - Dataset, the name of the dataset that you can use in variables in Switch.
 - Opaque dataset name, it is important that this property has the same name as the setting in the Opaque pickup elements “dataset name” property. If these two are not the same the job will fail.
- Include first line in the sheet
 - Yes, in this case the value of each column header will be used as a node tag in the XML, if the column header is “first_name” it will be like this:
<col name=”first_name”>John</col>
 - No, then the first line is not a header and the values of the first line will be treated as all other rows in the Excel file.

Property	Value
Name	Excel to XML
Description	
Path to script file	/Users/Shared/Scripts/xlsx2csv.py
Encoding in XML	UTF-8
Output mode	Convert Excel to XML
<i>One or many XML-files</i>	One XML file for all sheets
First line is header	Yes

Property	Value
Name	Excel to XML v7 beta
Description	
Path to script file	/Users/Shared/Scripts/xlsx2csv.py
Encoding in XML	UTF-8
Root node name	csv
Row node name	row
Column node name	col
Output mode	Convert Excel to XML
<i>One or many XML-files</i>	One XML file for each row
<i>First part of file name, column #</i>	1
<i>Second part of file name, column #</i>	
First line is header	Yes

Property	Value
Name	Excel to XML
Description	
Path to script file	/Users/Shared/Scripts/xlsx2csv.py
Encoding in XML	<div style="border: 1px solid gray; padding: 2px;"> <input checked="" type="checkbox"/> UTF-8 </div>
Output mode	<div style="border: 1px solid gray; padding: 2px;"> <input type="checkbox"/> iso-8859-1 Excel data as XML dataset </div>
<i>Dataset</i>	Excel XML
<i>Opaque dataset name</i>	Opaque
First line is header	Yes

A screenshot of a 'Properties' dialog box with a title bar containing three colored buttons (red, yellow, green) and the text 'Properties'. The dialog is divided into two columns: 'Property' and 'Value'. The following table represents the data shown in the dialog:

Property	Value
Name	Excel to XML
Description	
Path to script file	/Users/Shared/Scripts/xlsx2csv.py
Encoding in XML	UTF-8
Output mode	Attach opaque Excel data as XML dataset
<i>Dataset</i>	Excel XML
<i>Opaque dataset name</i>	Opaque
First line is header	Yes

A screenshot of a 'Properties' dialog box with a title bar containing three colored buttons (red, yellow, green) and the text 'Properties'. The dialog is divided into two columns: 'Property' and 'Value'. The following table represents the data shown in the dialog:

Property	Value
Name	Opaque pickup
Description	
Dataset name	Opaque
Pickup mode	Metadata alongside asset
<i>Metadata filename pattern</i>	*.xlsx
<i>Orphan timeout (minutes)</i>	15

In the Opaque pickup element you have to set the properties as in the image above. Pickup mode must be “Metadata alongside asset”. And the “Metadata filename pattern” must be set to *.xlsx. In this property pane you can set the Dataset name for the Opaque pickup. It must be exactly the same here as you set in the Excel to XML property “Opaque dataset name”. If not the job will fail.

Extra information

If you use this app to output multiple XML files for later import in to InDesign for automatic production of documents you will need to adapt the XML to something useful for InDesign. To do that you have to use the Saxonica configurator and an XSLT-file. This will give you the possibility to produce business cards, tickets or product labels very quickly. You can do this without the Switch Metadata module.

To better process the resulting PDF-files that you have made with the XML-files from the app there is now two Private data that will help you.

- Private data key: **SheetId**
 - This key will give you the name of the Excel sheet where the XML-data comes from.
- Private data key: **NumberOfRecords**
 - This key will give you the number of records that are picked up from the Excel sheet.

When you later in the flow will need to assemble the produced single PDF-files from each record these two Private data keys are needed.

In the Assemble job properties you will use the scheme “Custom” and then use the SheetId key as a job identifier and the property “Number of files” from the key “NumberOfRecords”

The XML structure for the multiple XML-files will have the X-path structured per each row and each column as follows: /csv/row/col

Here is an example of an XSLT-file that can be used with the XML-files you get from the Excel to XML app. Each XML-file will have the name of the Excel workbook sheet.

XSLT example

Be aware that this might lead to overwriting XML-files where the default sheet name is used.

Note, with the new function in version 7 you don't need an XSLT to split XML-files to get one XML for each row.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="2.0">
  <xsl:output method="xml" indent="yes"/>
  <xsl:template match="/">
    <xsl:apply-templates/>
  </xsl:template>
  <!--Splits the XML-file generated in to single XML-files, one for each row-->
  <xsl:template match="/csv">
    <xsl:for-each select="row">
      <!-- Selects which column value to use as filename for the resulting single XML-file. -->
      <!-- In this case column 2 is used. -->
      <xsl:variable name="filename"><xsl:value-of select="col[2]"/>.dita </xsl:variable>
      <xsl:result-document href="{col[2]}.xml" method="xml">
        <excel-row>
          <!--List the columns from the Excel-file in the order they will have in the resulting XML-file.-->
          <!--The name can be set to anything you like, for example the header used in Excel.-->
          <col name="Column 1">
            <xsl:value-of select="col[3]"/>
          </col>
          <col name="Column 2">
            <xsl:value-of select="col[4]"/>
          </col>
          <col name="Column 3">
            <xsl:value-of select="col[5]"/>
          </col>
          <col name="Column 4">
            <xsl:value-of select="col[6]"/>
          </col>
          <col name="Column 5">
            <xsl:value-of select="col[2]"/>
          </col>
        </excel-row>
      </xsl:result-document>
    </xsl:for-each>
  </xsl:template>
</xsl:stylesheet>
```

If you choose to attach the Excel data to a job file as a dataset the XML structure will be as follows: /workbook/sheet/csv/row/col were each sheet node will have the name of the sheet.

Third party information

This app uses a Python script that is published under GPL2 licenses. The script can be downloaded from the Excel to XML page in the Enfocus App store, place the file ***xlsx2csv.py*** in a folder of your choice on the same system as your Switch server. In the properties you then select this file for the app to work.

The app requires Python 2.7 to run the above mentioned script, for Windows it is embedded in the app, in Mac OSX Python 2.7 is already installed in the system. [Python 2.7 license can be read here.](#)

New in version 2

Python script is no longer embedded due to licensing issues.

Better XML if first line is header.

New in version 3

App can now handle a one column Excel-file.

New in version 5

Two options to use Private data.

New in version 6

Option to set encoding in output XML.

New in version 7

Save one XML-file for each row in the Excel sheet, it is restricted to only one sheet in the Excel file. If there are any more sheets the job will fail.

Naming the nodes in the XML output.
